## Mean BMI Ratings and the Wealth of a Country

## Introduction-

Obesity is a hot topic in today's world- with over 69.2\% of adults in America being overweight, and a percentage of children being close behind. America is often referred to as the most overweight country. I work in a grocery store and am able to see the relationship between the kinds of foods that people buy (healthy vs. unhealthy, processed, natural) and whether they use government assistance to pay for it. Many times, but not all of the time, people whom use government assistance tend to buy more processed food, which tends to be less healthy. After seeing this relationship and doing a little research I made sense of this thought. Many Americans with low income tend to work more to make ends meet, and therefore do not have time to cook healthy meals for their family, causing them to eat snack food or fast food. Also, processed, unhealthy food often tends to be a lot cheaper then, say, organic completely natural food, so many people can not afford such healthy food. At first I wanted to study these patterns within American culture, but because of lack of data, I decided to study this on a worldly scale. I was led to think about what factors play into the overall health and obesity of citizens in a country. Does the wealth of a country determine how much the inhabitants have to eat, and in turn, determine their body mass index rating?

BMI is a number that is an indicator of body fatness, calculated from a persons weight and height. This is often a reliable number proven by other hi-tech, expensive procedures. A BMI measure of below 18.5 correlates to being underweight, from $\leq 18.5-24.9$ correlates to being a healthy weight, $25.0-29.9$ correlates to being overweight, and $\geq 30.0$ correlates to being obese. (About BMI for Adults)
Why less than or equal to?

In this investigation I will compare the mean female BMI's of almost 140 countries to the GDP (gross domestic product) per capita PPP (purchasing power parity) in current international dollars. International dollars are a conversion of the money in each country that has the same purchasing power over GDP as the U.S. dollar has in the Unites States. GDP per capita based on purchasing power parity is a gross domestic product, converted to international dollars, that is the sum of gross value added by all resident producers in the economy plus any product taxes and minus any subsidies not included in the value of the products. Basically, this is a measure of the wealth of the country and an indirect measure of the wealth of the common person, commonly used to compare. (Amadeo) (Purchasing Power Parity)

My aim in this investigation is to see if there is a relationship between the wealth of a particular country and the average BMI of the female in that country.

## Investigation-

I will compare the mean BMI's of each country to the GDP per capita PPP of the country. The BMI's are taken from women ages 15-49. (The World Bank) (World Health Organization)

87860.31

After attaining this data, I graphed the GDP of the country vs. the average BMI. The graph is as follows-

## Calculations of results

I will use math to see if there is a relationship between the financial income of various countries and the mean female BMI within that country.
A. Linear Regression/Line of Best Fit

The linear regression line is also the line of best fit- it shows the general trend in the data.
Equation-

$$
\longleftarrow \text { A- This is very difficult to read. }
$$

$$
\begin{aligned}
& y=m x+b
\end{aligned}
$$

1. First, find the slope

( $\sum x y$ ) Is the sum of $x^{*} y$ of each point. This is the number at the bottom of the sixth last column.
$\left(\sum x\right)\left(\sum y\right)$ is the product of the sum of the $x$ 's and the sum of the $y$ 's (second column, last row multiplied by third column, last row)
( $\sum x^{2}$ ) Is the x of each point squared. You then add all of these numbers to get the sum. This is the number at the bottom of the fourth column.
$\left(\sum x\right)^{2}$ Is the sum of all of the x 's, and then this number is squared. This is the number at the bottom of the second column, squared.
n is the total number of data points in the investigation, or 138
Slope $-m=\frac{n(43247829.9)-(1654427)(3467.5)}{n(45877627393)-(1654427)^{2}}$
Slope - m $=\frac{(1.38)(43247829.9)-5736725622.5}{(138)(45877627393)-27371286988329}$
Slope $=m=\frac{5968200526.2-5736725622.5}{6331112580234-27371.286988329}$
Stope $-m=\frac{231474903}{3593983881905}$
$m=0.0000644062164178$
2. Next, find intercept.
intercepx $-b=\frac{\left(\sum y\right)-m\left(\sum x\right)}{n}$
( $\sum y$ ) Is the sum of all the $y$ 's. This is the number at the bottom of the third column.
( $\sum x$ ) Is the sum of all the x 's. This is the number at the bottom of the second column.
n is the total number of data points in the investigation.

$b=24.354671134$
3. Put it together for full equation

Full Equation of line-

$$
y=.0000644 x+24.35
$$

Scatter plot with included linear regression-

B. Find the "R" value- this value shows how well the data actually fits into the calculated linear regression line. If the number is close to 1 (positive slope) or -1 (negative slope) then the line fits the data well. As the R value gets closer to 0 , the linear regression line and the data do not fit each other as well.

1. Find the value-

! $x y$ ) is the sum of $x^{*} y$ of each point. This is the number at the bottom of the sixth last column.
( $\left.\sum x\right)\left(\sum y\right.$ ) is the product of the sum of the $x$ 's and the sum of the $y$ 's (second column, last row multiplied by third column, last row)
$\left(\sum^{x^{5}}\right)$ Is the x of each point squared. You then add all of these numbers to get the sum. This is the number at the bottom of the fourth column.
r $\left.\sum x\right)^{2}$ Is the sum of all of the $x$ 's, and then this number is squared. This is the number at the bottom of the second column, squared.
( $\sum^{y} y^{\bar{i}}$ ) Is the y of each point squared. You then add all of these numbers to get the sum. This is the number at the bottom of the fifth column.
( $\left.\sum_{x} x\right)^{2}$ Is the sum of all of the $x$ 's, and then this number is squared. This is the number at the bottom of the second column, squared.
n is the number of data points in the investigation.

$$
\text { coefficientofcorrelation }-r=\frac{n\left(\sum x y\right)-\left(\sum x\right)\left(\sum y\right)}{\left[n\left(\sum x^{2}\right)-\left(\sum x\right)^{2}\right]^{s}\left[n\left(\sum y^{2}\right)-\left(\sum y\right)^{2}\right]^{s}}
$$

$$
\begin{aligned}
& F_{m}(138)(138)(43247829,96) \times 5736735623.5
\end{aligned}
$$

$\left(\sum^{5} x\right)^{2}$ Is the sum of all of the $x$ 's, and then this number is squared. This is the number at the bottom of the second column, squared.
 the sum. This is the number at the bottom of the fifth column.
? $\left.\sum^{5} x\right)^{3}$ Is the sum of all of the $x$ 's, and then this number is squared. This is the number at the bottom of the second column, squared.
n is the number of data points in the investigation.

$$
\text { coefficientofcorrelation }=r=\frac{n\left(\sum x y\right)-\left(\sum x\right)\left(\sum y\right)}{\left[n\left(\sum x^{2}\right)-\left(\sum x\right)^{2}\right]^{5}\left[n\left(\sum y^{2}\right)-\left(\sum y\right)^{2}\right]^{s}}
$$

$$
I=\frac{2314740[8]}{[3593983881.905]}
$$

$$
=\frac{231474903}{x / 2333335.423}
$$

$$
R=0.383882
$$

## Conclusion-

To show a strong correlation, the R value should be close to 1 for a positively sloped line, and close to -1 for a negatively sloped line. The closer the R value is to zero, the less correlated the data is. Since the R value is a very small number, very close to zero ( 0.383882 ), we know that the data barley correlates.

Why is this? One may think that there should be an obvious correlation between how much money a person has and how much food they are able to buy, which would mean, in

$$
\begin{aligned}
& \text { Fon (138)(43757829,9) }-5736725623.5
\end{aligned}
$$
